CSE 360-Computer Architecture

Lecture-2

Dr. Shamim Akhter

Associate Professor

Department of Computer Science and Engineering
email: shamimakhter@ewubd.edu

When would you want to compare performance between different computers?

Performance Metrics

- Purchasing perspective
 - given a collection of machines, which has the
 - best performance ?
 - least cost ?
 - best cost/performance?
- Design perspective
 - faced with design options, which has the
 - best performance improvement ?
 - least cost ?
 - best cost/performance?
- Both require
 - basis for comparison
 - metric for evaluation

- Our goal is to understand what factors in the architecture contribute
 - to overall system performance
 - relative importance (and cost) of these factors.

What ways can be used to determine perform on a desktop PC?

What ways can be used to determine perform on a server?

Computer Performance: TIME, TIME, TIME!!!

- Response Time (elapsed time, latency):
 - how long does it take for my job to run?
 - how long does it take to execute (start to finish) my job?
 - how long must I wait for the database query?
- Throughput:
 - how many jobs can the machine run at once?
 - what is the average execution rate?
 - how much work is getting done?

Individual user concerns...

Systems manager concerns...

- If we upgrade a machine with a new processor what do we increase?
- If we add a new machine to the lab what do we increase?

- •What ways can be used to determine perform on a desktop PC?
- •What ways can be used to determine perform on a server?

Throughput and Response Time

- Q1. If we upgrade a machine with a (faster) processor, what do we increase?
- Q2. Adding additional processors to a system that uses multiple processors for separate tasks-searching web
- Q1 Answer: Response Time Decrease->Improve throughput
- Q2 Answer: Only throughput increase.
- However, demand for processing is as large as throughput process stores @ Queue then improve response time as reducing wait time

Execution Time

Elapsed Time

- counts everything (disk and memory accesses, waiting for I/O, running other programs, etc.) from start to finish
- a useful number, but often not good for comparison purposes elapsed time = CPU time + wait time (I/O, other programs, etc.)

Time spent in user space

Time spent in kernel space-

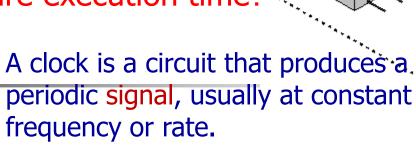

CPU time

- doesn't count waiting for I/Oor time spent running Other programs
- can be divided into user CPU time and system CPU time (OS calls)
 CPU time = user CPU time + system CPU time
- ⇒ elapsed time = user CPU time + system CPU time + wait time
- Our focus: user CPU time (CPU execution time or, simply, execution time)
 - time spent executing the lines of code that are in our program

Clock Cycles

seconds

How do you measure execution time?

quartz crystal

analog to digital

conversion

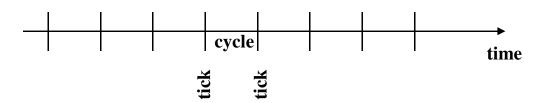

Hardware events progress cycle by cycle:

 in other words, each event, e.g., multiplication, addition, etc., is a sequence of cycles

$$\frac{\text{seconds}}{\text{program}} = \frac{\text{cycles}}{\text{program}} \times \frac{\text{seconds}}{\text{cycle}}$$

Clock ticks indicate start and end of cycles:

cycle time = time between ticks = seconds per cycle

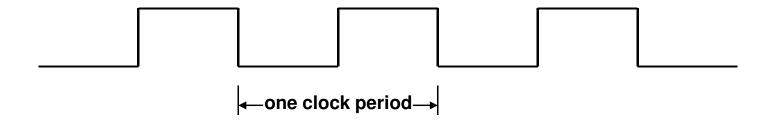

NB: Clock ticks =smallest unit of time recognized by a device. Ex. 66MHz = 66 million clock ticks per second.

Clock Rate

Clock rate (MHz, GHz) is inverse of clock cycle time (clock period)

$$CC = 1 / CR$$

clock rate (frequency) = cycles per second (1 Hz. = 1 cycle/sec, 1 MHz. = 10^6 cycles/sec)

Example: A 200 Mhz. clock has a cycle time

$$\frac{1}{200 \times 10^6} \times 10^9 = 5 \text{ nanosecor.}$$

Improves
by reducing <
execution time

For some program running on machine X:

 $Performance_X = 1 / Execution time_X$

X is n times faster than Y means:

 $Performance_{X} / Performance_{Y} = n$

Performance Equation I

$$\frac{\text{seconds}}{\text{program}} = \frac{\text{cycles}}{\text{program}} \times \frac{\text{seconds}}{\text{cycle}}$$

equivalently

- So, to improve performance one can either:
 - reduce execution time
 - reduce program cycles, or
 - reduce the clock cycle time, or, equivalently, increase the clock rate

- Our favorite program runs in 10 seconds on computer A, which has a 400Mhz. clock.
- We are trying to help a computer designer to build a new machine B, that will run this program in 6 seconds. The designer can use new (or perhaps more expensive) technology to substantially increase the clock rate, but has informed us that this increase will affect the rest of the CPU design, causing machine B to require 1.2 times as many clock cycles as machine A for the same program.
- What clock rate should we tell the designer to target?

4

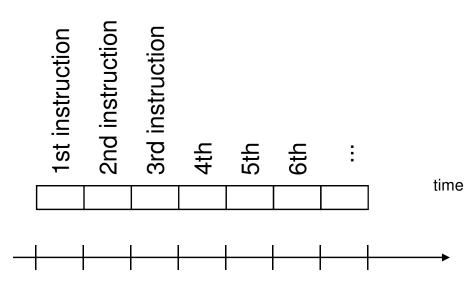

Can we predict the execution time, without running in CPU?

Assume: # of instruction = # of cycles

Assumption is incorrect!

Could assume that # of cycles = # of instructions

Because:

- Different instructions take different amounts of time (cycles)
- Multiplication takes more time than addition
- Floating point operations take longer than integer ones
- Accessing memory takes more time than accessing registers

They have different execution steps [Datapath]

Solution

- Execution time is equals to
- # of instructions executed X the average time per instruction

Performance Equation II

CPU execution time for a program

CPU clock cycles for a program

Clock cycle time

X

CPU clock cycles = # Instructions x Average clock cycles for a program x per instruction

CPU execution time = Instruction count × average CPI × Clock cycle time for a program for a program

- Clock cycles per instruction (CPI) the average number of clock cycles each instruction takes to execute
 - A way to compare two different implementations of the same ISA

	CPI for this instruction class				
	Α	В	С		
CPI	1	2	3		

- Suppose we have two implementations of the same instruction set architecture (ISA). For some program:
 - machine A has a clock cycle time of 10 ns. and a CPI of 2.0
 - machine B has a clock cycle time of 20 ns. and a CPI of 1.2

Which machine is faster for this program, and by how much?

Effective CPI

Computing the overall effective CPI is done by looking at the different types of instructions and their individual cycle counts and averaging

Overall effective CPI =
$$\sum_{i=1}^{n} (CPI_i \times C_i)$$

- Where C_i is the count (percentage) of the number of instructions of class i executed
 - C_i not in %, the above equation will be divided by total Ic
- CPI_i is the (average) number of clock cycles per instruction for that instruction class
- n is the number of instruction classes

A Simple Example – calculate average CPI

		_

Ор	Freq	CPI _i	Freq x CPI _i
ALU	50%	1	
Load	20%	5	
Store	10%	3	
Branch	20%	2	
Over	$\Sigma =$		

Ор	Freq	CPI _i	Freq x CPI _i
ALU	50%	1	.5
Load	20%	5	1.0
Store	10%	3	.3
Branch	20%	2	.4
Over	$\Sigma = 2.2$		

	ı	
	ı	
	ı	
	٠	

Ор	Freq	CPI _i	Freq x CPI _i
ALU	50%	1	
Load	20%	5	
Store	10%	3	
Branch	20%	2	
Over	$\Sigma =$		

- How much faster would the machine be if a better data cache reduced the average load time to 2 cycles?
- How does this compare with using branch prediction to save a cycle off the branch time?
- What if two ALU instructions could be executed at once?

Ор	Freq	CPI _i	Freq x CPI _i	Q1
ALU	50%	1	.5	.5
Load	20%	5	1.0	.4
Store	10%	3	.3	.3
Branch	20%	2	.4	.4
Over	all effect	$\Sigma = 2.2$	1.6	

How much faster would the machine be if a better data cache reduced and replaced the average load time to 2 cycles?

Ор		Freq	CPI _i	Freq x CPI _i	Q1
ALU		50%	1	.5	.5
Load		20%	5	1.0	.4
Store		10%	3	.3	.3
Branch		20%	2	.4	.4
	Over	all effect	$\Sigma = 2.2$	1.6	

How much faster would the machine be if a better data cache reduced and replaced the average load time to 2 cycles?

CPU time new = $1.6 \times IC \times CCT$ so 2.2/1.6 means ($1.375 \times 1.5\%$) faster

(Notice that 2.2 x IC x CCT / 1.6 x IC x CCT = 2.2/1.6, since the IC and CCT

remain unchanged by adding a bigger cache)

•	Ор	Freq	CPI _i	Freq x CPI _i	Q2	
	ALU	50%	1	.5	.5	
	Load	20%	5	1.0	1.0	
	Store	10%	3	.3	.3	
	Branch	20%	2	.4	.2	
	Overall effective CPI			$\Sigma = 2.2$	2.0	

How does this compare with using branch prediction to save a cycle off the branch time?

				_
Ор	Freq	CPI _i	Freq x CPI _i	Q2
ALU	50%	1	.5	.5
Load	20%	5	1.0	1.0
Store	10%	3	.3	.3
Branch	20%	2	4	

Overall effective CPI $| \Sigma = 2.2$

How does this compare with using branch prediction to save a cycle off the branch time?

CPU time new = $2.0 \times IC \times CCT$ so 2.2/2.0 means (1.1 times)10% faster

2.0

_					
	Ор	Freq	CPI _i	Freq x CPI _i	Q3
	ALU	50%	1	.5	.25
	Load	20%	5	1.0	1.0
	Store	10%	3	.3	.3
	Branch	20%	2	.4	.4
	Over	all effect	$\Sigma = 2.2$	1.95	

What if two ALU instructions could be executed at once?

Ор	Freq	CPI _i	Freq x CPI _i	Q3
ALU	50%	1	.5	.25
Load	20%	5	1.0	1.0
Store	10%	3	.3	.3
Branch	20%	2	.4	.4
Over	all effect	$\Sigma = 2.2$	1.95	

What if two ALU instructions could be executed at once?

CPU time new = $1.95 \times IC \times CCT$ so 2.2/1.95 means (1.128 times) 12.8% faster

	Ор	Freq	CPI _i	Freq x CPI _i	Q1	Q2	Q3
	ALU	50%	1	.5	.5	.5	.25
	Load	20%	5	1.0	.4	1.0	1.0
	Store	10%	3	.3	.3	.3	.3
	Branch	20%	2	.4	.4	.2	.4
	Overall effective CPI			$\Sigma = 2.2$	1.6	2.0	1.95

How much faster would the machine be if a better data cache reduced and replaced the average load time to 2 cycles?

CPU time new = $1.6 \times IC \times CCT$ so 2.2/1.6 means 37.5% faster

How does this compare with using branch prediction to save a cycle off the branch time?

CPU time new = $2.0 \times IC \times CCT$ so 2.2/2.0 means 10% faster

What if two ALU instructions could be executed at once?

CPU time new = $1.95 \times IC \times CCT$ so 2.2/1.95 means 12.8% faster

CPI Example II

A compiler designer is trying to decide between two code sequences for a particular machine. The hardware designers have supplied the following facts:

	CPI for this instruction class				
	A	В	С		
CPI	1	2	3		

For a particular high-level-language statement, the compiler writer is considering two code sequences that requires the following instruction counts:

	Instruction counts for instruction class				
Code sequence	A	В	С		
1	2	1	2		
2	4	1	1		

• Which sequence will be faster? How much? What is the CPI for each sequence?

MIPS Rate (Millions of Instructions per Second)

MIPS Rate =
$$\frac{Ic}{T \times 10^6} = \frac{f}{CPI \times 10^6}$$

MFLOPS Rate =
$$\frac{\text{Number of executed floating - point operations in a program}}{\text{Execution time x } 10^6}$$

Example III

Consider the execution of a program that results in the execution of 2 million instructions on a 400-MHz processor. The program consists of four major types of instructions. The instruction mix and the CPI for each instruction type are given below based on the result of a program trace experiment:

Instruction Type	CPI	Instruction Mix (%)
Arithmetic and logic	1	60
Load/store with cache hit	2	18
Branch	4	12
Memory ref	8	10

Find the MIPS rate?

Performance Depends on the algorithm, programming language, Compiler, ISA

Execution Time Depends on instruction counts, CPI, Clock Cycle time

Instruction Counts Depends on ISA, Programmer effective coding, Compiler

code optimization

CPI ISA, H/W Organization

Clock Cycle Time H/W Organization, Implementation strategies

Amdahl's Law

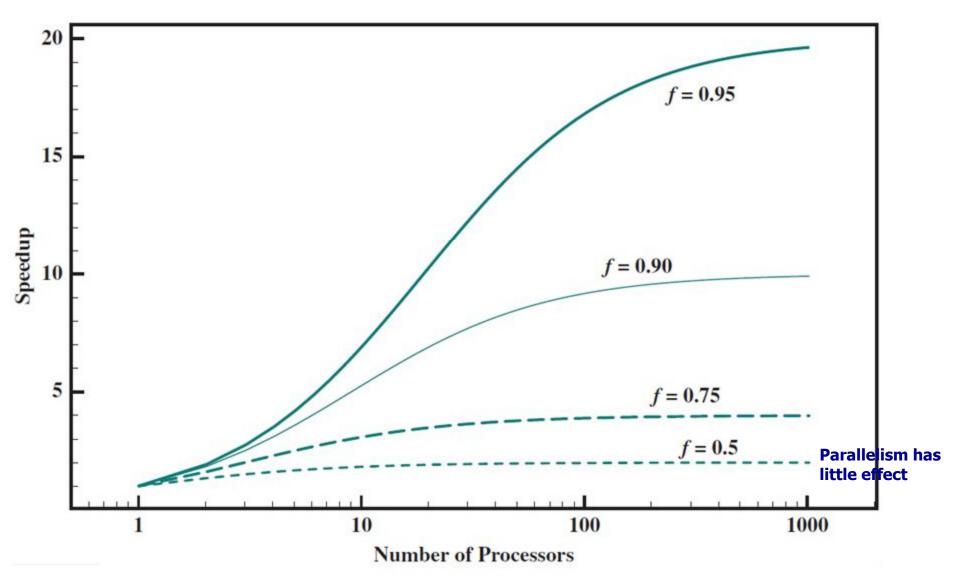

Potential speedup using multiple processors environment

Consider a program running on a single processor such that a fraction (1-f) of the execution time involves code that is inherently serial and a fraction f that involves code that is infinitely parallelizable with no scheduling overhead. T is the total execution time of the serial program. Then Speedup using N processors is as follows:

$$Speedup = \frac{Time \text{ to execute program on a single processor}}{Time \text{ to execute program on N parallel processors}}$$

$$= \frac{T(1-f) + Tf}{T(1-f) + \frac{Tf}{N}} = \frac{1}{(1-f) + \frac{f}{N}}$$
 N -> Inf Height possible speed up bound to 1/(1-f)

Amdahl's Law for Multiprocessors

Chapter 3 @Computer Organization and Architecture, William Stallings
